6 Declaration

- I, Pau Miquel Mir, declare that this thesis and the work presented in it are my own and has been generated by me as the result of my own original research. I confirm that:
 - 1. This work was done wholly or mainly while in candidature for a degree at this University;
 - 2. Where any part of this thesis has previously been submitted for any other qualification at this University or any other institution, this has been clearly stated;
 - 3. Where I have consulted the published work of others, this is always clearly attributed;
 - 4. Where I have quoted from the work of others, the source is always given. With the exception of such quotations, this thesis is entirely my own work;
 - 5. I have acknowledged all main sources of help;
 - 6. Where the thesis is based on work done by myself jointly with others, I have made clear exactly what was done by others and what I have contributed myself;
 - 7. None of this work has been published before submission.

19	Acknowledgements
20	I want to thank my advisor, Dr. Edward Richardson, for his time and dedication.
21	Furthermore, I would like to thank Vishagen Ramasamy for his initial work upon which this
22	paper builds.
23	I also want to thank my parents, for their constant support and for proofreading the paper.

24 Abstract

This is the abstract.

1 Introduction

{sec:introduction}

1.1 Purpose of the investigation

Hydrogen is a very promising alternative fuel for the future, mainly due to the absence of greenhouse emissions when burning it. In this regard, it is superior to current petroleum-, and more generally, carbon-based fueling systems. However, air pollution is a negative externality associated with carbon-based fuels, as it is a cost to a third party (in this case, society as a whole) that is not accounted for in the price of the good. By definition, the negative consequences of polluting the air are not accounted for in the price of carbon vehicles, and therefore will have little influence on a consumer's choice. Thus, if hydrogen is to succeed as an alternative to carbon fuels, it is essential that its use be as - if not more - convenient than traditional fuel.

One of the main aspects that currently lags behind traditional fuel is the refueling experience. Given that refueling hydrogen involves its compression, there is a significant rise in temperature, which must be kept below certain standards (358K as per SAE J2601). This in turn leads to long refueling times, potentially lasting more than five minutes, which is cumbersome for users. Therefore, it is of prime importance to research and develop systems that enable the faster refueling of hydrogen cylinders. To this end, this project will build upon a model of filling a hydrogen cylinder which has already been developed by members of the department in order to analyse novel methods of improving fill times.

1.2 Outline of the investigation

instead regulate the gas temperature.

One of the current solutions to improve fill times involves cooling the hydrogen before filling the cylinder as to keep it below he maximum temperature. However, this is quite expensive, both in energy terms and in economic terms. Consequently, the aim of this project is to continue exploring several of the options available to reduce fill times and simultaneously reduce the energy consumption of the process, thus improving both convenience for users and energy efficiency of the fueling stations. Indeed, by building upon the existing cylinder model several options shall be considered, namely: refrigeration, flow regulation, heat sink usage, active cooling, heat pipe usage, and phase change materials. From here, several options are open to further deepen or potentially broaden the investigation. An attempt to further simplify the model can be made, perhaps even reducing it so a simple algebraic relationship. Also, the model would benefit from FEA validation to aid our understanding of the heat transfer in the structure. This would go hand in hand with analyzing the temperature of the structure, and see how close this matches the gas temperature. Indeed, if the structure is at a much lower temperature than the gas, the case can be made that the current regulations are slightly erroneous, as they are meant to protect the materials of the structure, but

Update with actual options considered at end of project

2 **Background**

kground}

98

Vehicles and objectives

We must firstly consider what real-world relevance of this project is. As explained in Section 1, the hydrogen cylinders being considered are for road vehicles. 100

2.1.1 **Material constraints**

The main reason that a problem exists, and consequently this paper (and much other work) is being 102 undertaken, is the material limitations that exist in hydrogen cylinders. Indeed, the cylinders that 103 are used for high pressure scenarios such as the one we are presented with, are constructed with a 104 composite material such as carbon fibre or glass/aramid fibre. In addition, they have a liner that is 105 made out of metal, typically aluminum, in Type III cylinders, and out of a thermoplastic material for 106 Type IV cylinders. Of concern is the composite material, as the polymer matrix cannot withstand 107 high temperatures, and as such the material properties of the cylinder will begin to degrade. The 108 specific temperature at which this occurs is usually around the glass transition temperature of the 109 epoxy, where the thermosetting polymer changes from a hard "glassy" state to a more compliant 110 "rubbery" state.

2.2 **Previous work** 112

We must first establish a baseline of previous work that has been conducted in this field, and subse-113 quently analyze the shortcomings that exist in order to direct the research. 114

Modeling Work 2.2.1 115

A large amount of research has been conducted using multidimensional analysis, especially using 116 Computational Fluid Dynamics (CFD). Indeed, there is myriad papers describing different methods and setups, such as Dicken and Mérida's work, which uses the standard k- ε turbulence model and the Redlich-Kwong real gas equation of state for real gas properties [1]. Some of these models use more 119 advanced property models, such as the model presented by Zhao et al., which employs REFPROP 120 (see Section 2.5.3) in order to have more precise real gas properties [2]. 121

2.2.2 Experimental work

122

127

{sec:experimental_v

Several papers describe experimental work that has been conducted regarding the fast-filling of 123 hydrogen cylinders, in particular comparing the results to simulations. Dicken and Mérida's work 124 indicates that the temperature inside the cylinder is rather uniform [3]. This claim is not, however 125 supported by the work of Zheng et al nor that of Woodfield et al [4], wherein large discrepancies 126 among gas temperatures in different regions of the cylinder are found.

Citation

28 **2.2.3** Analysis

The simulation work that has been conducted can be, in broad terms, divided into complex CFD models and more simplified 0-dimensional models. It is important analyze the difference between these two systems. The main advantage of reduced dimension models is that they are much less computationally expensive. This, in turn, means it can be incorporated as part of a larger analysis, in which it must be run multiple times, such as optimization routines or probabilistic whole station models.

Reduced dimension models assume a constant gas temperature, which, as outlined in Section 2.2.2, is supported by some experimental work, but refuted by others. For this reason, more research should be conducted to validate the uniform gas temperature approximation.

2.3 Cylinder filling models

Several ways of modeling the cylinder can be considered when analysing their filling, with varying complexity and accuracy.

141 **2.3.1 Zonal**

A zonal model, also referred to as a 0-dimensional model, refers to models that consider the gas inside the cylinder as the control volume, with homogenous properties. This allows for simpler calculations,

145 2.3.2 Multidimensional

More complex multidimensional models can be created, either 2D axisymmetric models or full 3D models. 2D models will not include the effects of gravity or buoyoncy, but

148 2.4 Heat transfer models

In order to successfully analyze the behaviour of the system as a whole we must consider several local heat transfer methods that occur at different places inside of the cylinder.

2.4.1 Impinging jet

The first behaviour that we will consider is that of an impinging jet of fluid onto a surface.

FIGURE 1: Impinging jet

$\{ exttt{fig:inpinging_jet} \}$

2.4.2 Pipe flow

A second behaviour that we will consider is that of pipe flow. This behaviour has been the focus of much research, as it is arguably the most common mode of heat transfer that occurs in most fluid systems.

2.4.3 Turbulent Jets

157

162

163

164

178

179

180 181

182

183

184

185

Lastly, we must also consider turbulent jets, as there will be such a situation at the exit of the nozzle.

159 2.5 Methodology

Throughout the analysis that will be conducted several methods and techniques will be used. These are described in this section.

2.5.1 Optimization

2.5.2 Non-dimensioning

One of the fundamental principals used throughout this paper, and indeed, throughout engineering, is that of non-dimensioning. By operating using non-dimensional parameters such as the Reynolds number $Re = \frac{\rho uL}{v}$ or the Prandtl number $Pr = \frac{c_p \mu}{k}$ solving problems involving differential equations becomes simplified. Also, the analysis becomes much more general, and can be scaled.

Fill Section once work on optimization starts.

{sec:numerical_meth

169 2.5.3 Numerical methods

Integrating ODEs An central part of solving unsteady heat transfer problems involves integrating ODEs, as will be seen in Section 3. One of the simplest methods available, both conceptually and in terms of ease of implementing in code, is forward Euler time integration. It can be informally described as follows: given a function that can be defined by:

$$y'(t) = f(t, y(t)), \quad y(t_0) = y_0$$
 (2.1)

we can compute the approximate shape of the function given the initial point and finding the slope of the curve for small intervals. Indeed, from the initial point, we can find the tangent of the curve at that point, and take a small step along that tangent until arriving at the next point, where the procedure can be repeated. Denoting the step size h, we can express forward Euler time integration as:

$$y_{n+1} = y_n + hf(t_n, y_n)$$
 (2.2)

{sec:property_model

Property models As the gases that are being treated in this report are at very high pressures, ideal gas approximations are inaccurate, and thus real gas properties must be employed. To this end, property models must be used, which can determine any gas property from two other independent properties.

The property model that will be employed throughout this analysis is REFPROP, a tool developed by the National Institute of Standards and Technology [5]. It uses values of critical and triple points together with equations for the thermodynamic and transport properties to calculate the state points of fluids.

3 Formulation

{sec:formulation}

Citation

3.1 Heat transfer across cylinder

The main mode of heat transfer that occurs in the cylinder and that will be used throughout this report is heat conduction through the wall of the cylinder. This is modeled using:

$$\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2} \tag{3.1}$$

where a is the thermal diffusivity, which is defined by :

$$\alpha = \frac{k}{\rho c} \tag{3.2}$$

where k is the material's thermal conductivity, ρ is the density of the material, and c is the specific heat capacity of the material.

This differential equation will be solved using forward Euler time integration as described in Section 2.5.3

195 3.2 Gas flow into cylinder

The nozzle and corresponding gas flow will be modeled using isentropic relations, and then a discharge coefficient relationship will be used to find the approximate real values. Indeed, the isentropic Reynold's number is first calculated as follows:

$$Re_{ideal} = \frac{\rho_{exit} d_{inlet} u_{exit}}{\mu_{exit}}$$
 (3.3)

where ρ_{exit} , d_{inlet} , u_{exit} , and μ_{exit} are determined using real gas models as described in Section 2.5.3. In order to find the real mass flow an empirical discharge coefficient is employed:

$$CD = \frac{\dot{m}_{\text{in}}}{\dot{m}_{\text{ideal}}} = A + B \operatorname{Re}_{\text{ideal}}$$
 (3.4)

A discharge coefficient must be used to account for the formation of a boundary layer inside the inlet tube. The empirical model that was used was obtained from, and uses the following values:

5

$$A = 0.938, \quad B = -2.71 \tag{3.5}$$

203 3.3 Hysteresis

204 3.4 Throttling
